AU1

6 **Definition**

AU2

7 Implementation intentions are if-then plans that
 8 spell out in advance how one wants to strive for a
 9 set goal. For the if-component, a critical cue is
 10 selected (e.g., a good opportunity, an anticipated
 11 obstacle) that is linked to a goal-directed response
 12 in the then-component. Implementation intentions
 13 are known to enhance the rate of goal attainment.
 14 They do so by delegating action control to situa-
 15 tional cues thus endowing action control with
 16 features of automaticity.

17 **Description**

18 Successful goal pursuit requires solving both of
 19 two subsequent tasks: first strongly committing to
 20 goals and then effectively implementing them.
 21 Accordingly, strongly committing to a goal is a
 22 necessary but not sufficient step toward goal
 23 attainment. Indeed, effective goal pursuit may be
 24 hampered by various problems such as failing to
 25 get started and to stay on track as well as over-
 26 extending oneself. Finally, people may fail to
 27 disengage from futile means and unattainable

goals. Meta-analytic findings suggest that goals 28
 (also referred to as goal intentions) account for no 29
 more than 28% of variance in goal-directed 30
 behavior (Sheeran 2002). One remedy to impaired 31
 goal pursuit is – after one has strongly committed 32
 to a goal – to plan out in advance how one wants to 33
 deal with potential critical situations (i.e., by 34
 adding implementation intentions to one’s goal 35
 intentions). 36

Gollwitzer (1999) highlighted the importance 37
 of furnishing goal intentions with implementation 38
 intentions. While goal intentions (goals) have the 39
 structure “I intend to reach Z!” with Z relating to a 40
 desired future behavior or outcome, implementa- 41
 tion intentions have the structure “If situation X is 42
 encountered, then I will perform the goal-directed 43
 response Y!”; thus, implementation intentions 44
 define when, where, and how one wants to act 45
 on one’s goal intentions. In order to form an 46
 implementation intention, individuals need to 47
 identify a goal-relevant situational cue (such as a 48
 good opportunity to act or an obstacle to goal 49
 striving) and link it to an instrumental goal- 50
 directed response. Goal intentions merely specify 51
 a desired future behavior or outcome. On the 52
 contrary, the if-component of an implementation 53
 intention specifies when and where one wants to 54
 act on this goal, and the then-component of the 55
 implementation intention specifies how this will 56
 be done. For instance, a person with the goal to 57
 reduce alcohol consumption might form the fol- 58
 lowing implementation intention: “And whenever 59
 a waiter suggests ordering a second drink, then I’ll 60

ask for mineral water!” Empirical data supports the assumption that implementation intentions help close the gap between holding goals and attaining them. A meta-analysis based on close to a hundred studies shows a medium to large effect on increased rate of goal attainment ($d = 0.61$; Gollwitzer and Sheeran 2006).

Implementation intentions facilitate goal attainment on the basis of *psychological mechanisms* that pertain to the specified situation in the if-part and to the mental link forged between the if-part and the specified goal-directed response in the then-part of the plan (Gollwitzer and Oettingen 2016). Because forming an implementation intention implies the selection of a critical future situation, the mental representation of this situation becomes highly activated and hence more accessible. This heightened accessibility of the if-part of the plan has been observed in several studies using different experimental tasks (e.g., cue detection, dichotic listening, cued recall, lexical decision, flanker). However, forming implementation intentions not only heightens the activation (and thus the accessibility) of the mental presentation of the situational cue specified in the if-component, but it also forges a strong associative link between the mental representation of this cue and the mental representation of the specified response. These associative links seem to be quite stable over time, and they allow for activation of the mental representation of the specified response (the then-component) by subliminal presentation of the specified critical situational cue (if-component). Moreover, mediation analyses suggest that both cue accessibility and the strength of the cue-response link together mediate the impact of implementation intentions on goal attainment.

Gollwitzer (1999) suggested that the upshot of the strong associative links between the if-part (situational cue) and the then-part (goal-directed response) created by forming implementation intentions is that – once the critical cue is encountered – the initiation of the goal-directed response exhibits features of automaticity. These features include immediacy, efficiency, and redundancy of conscious intent. As a consequence, having formed an implementation

intention allows individuals to act in situ without having to deliberate on whether to act or not. Indeed, there is vast empirical evidence that if-then planners act more quickly, deal more effectively with cognitive demands (i.e., speedup effects still evidence under high cognitive load), and do not need to consciously intend to act in the critical moment. Consistent with this last assumption, implementation intention effects are observed even when the critical cue is presented subliminally or when the respective goal is activated outside of awareness.

The processes underlying implementation intention effects (enhanced cue accessibility, strong cue-response links, automation of responding) help if-then planners to readily see and to seize good opportunities to move toward their goals. Forming an if-then plan thus strategically automates goal striving. People can intentionally make if-then plans thus delegating control of goal-directed responses to preselected situational cues. This strategic automation hypothesis has recently been supported by studies that collected brain data using either electroencephalography (EEG) or functional magnetic resonance imaging (fMRI), suggesting that by forming implementation intentions people can switch from top-down control of their actions via goals to bottom-up control via specified situational stimuli. Research on mediating processes has also supported the strategic automation hypothesis, albeit in an indirect way. Numerous studies indicated that neither an increase in goal commitment nor an increase in self-efficacy qualified as potential alternative mediators of implementation intention effects.

But what about *potential moderators* of implementation intention effects on goal striving and goal attainment? Implementation intentions only benefit goal attainment when goal commitment is high; the same is true with respect to people's commitment to executing the formed implementation intention. Moreover, implementation intention effects are commonly observed to be stronger when the goal at hand is difficult rather than easy. Finally, self-efficacy was found to moderate implementation intention effects. Prompting participants to form an implementation intention as to when,

157 where, and how to pursue their most important
158 New Year's resolution (e.g., to engage in regular
159 physical exercise) and in addition reflect on past
160 mastery experiences (i.e., situations in which they
161 achieved a similar goal) led to significantly higher
162 levels of self-reported goal progress compared to a
163 mere implementation-intention condition. In a
164 recent study where high versus low self-efficacy
165 was manipulated (by asking participants to solve
166 low- or high-difficulty goal-relevant tasks), it was
167 observed that high-self-efficacy participants
168 showed stronger implementation intention effects
169 than low-self efficacy participants, especially when
170 the tasks to be solved were difficult rather
171 than easy.

172 Which aspects of goal striving have been found
173 to benefit from forming implementation intentions?
174 The effects of implementation intentions
175 have been demonstrated with respect to getting
176 started, staying on track, disengaging from faulty
177 goals and means, as well as avoiding resource
178 depletion. Implementation intentions were found
179 to help individuals to get started with goal striving
180 in terms of remembering to act (e.g., regarding
181 taking vitamin pills, contraceptive pills, influenza
182 vaccination), not missing opportunities to act
183 (e.g., regarding obtaining a mammography), and
184 overcoming an initial reluctance to act (e.g.,
185 regarding undertaking a testicular self-
186 examination). Moreover, goals to perform regular
187 breast examinations or cervical cancer screening
188 and to resume activity after joint replacement
189 surgery were all found to be more readily acted
190 upon by individuals who previously had formed
191 implementation intentions.

192 However, many health goals (e.g., eating a
193 healthy diet, regular physical exercise, reducing
194 alcohol consumption or smoking, downregulating
195 anxiety) cannot be accomplished by a simple,
196 discrete, one-shot action because they require
197 that people keep striving over an extended period
198 of time. Staying on track may then become very
199 difficult when certain internal stimuli (e.g., being
200 tired, stressed out) or external stimuli (e.g., temptations,
201 distractions) interfere with the desired
202 goal pursuit. Implementation intentions can be
203 used to protect started goal strivings from inter-
204 ferences stemming from both inside and outside

205 the person. Such implementation intentions may
206 use very different formats. For instance, if a per-
207 son with the goal to eat healthy foods wants to stay
208 firm with respect to seductive offers of unhealthy
209 snacks, she can form suppression-oriented imple-
210 mentation intentions, such as "And if my col-
211 league approaches me offering a snack, then
212 I will not take the snack!" The then-component
213 of such suppression-oriented implementation
214 intentions does not have to be worded, however,
215 as not showing the critical behavior (in the present
216 example "not taking the snack"); it may alterna-
217 tively specify a replacement behavior ("... , then
218 I will ask for an apple!") or focus on ignoring the
219 critical cue ("... , then I'll ignore her offer!").
220 Recent research suggests that mere negation
221 implementation intentions are less effective than
222 the latter two types of implementation intentions
223 (i.e., replacement and ignore implementation
224 intentions).

225 Two further types of implementation intentions
226 have been proven effective to master temptations
227 and disruptions. The first one specifies the tempt-
228 ation as a situational cue and links it to thinking
229 of the goal as the response in the then-component.
230 The second one specifies an ongoing activity –
231 that is independent of the temptation – as a situa-
232 tional cue and links it to continuing this activity as
233 the response in the then-component. Using, again,
234 the example of a person who has to cope with a
235 seductive offer from a colleague, let us assume
236 that the person already anticipated receiving the
237 tempting offer during an upcoming encounter
238 with a colleague; she therefore formed an imple-
239 mentation intention stipulating in advance what
240 she will converse about when she runs into her.
241 The interaction with the colleague can then come
242 off as planned as the seductive offer won't have a
243 chance to disrupt the course of action (i.e., the
244 conversation).

245 Goal striving that is no longer promising may
246 require individuals to disengage from a chosen
247 means or the goal altogether. Such disengagement
248 can free up resources and minimize negative
249 affect. However, individuals often stick to a cho-
250 sen goal or means too long thus hurting them-
251 selves (e.g., setting a too demanding exercise
252 goal, choosing improper means to reach the

253 goal). Implementation intentions can be used to
254 promote adaptive disengagement by (1) specifying
255 negative feedback as a critical cue and (2) linking
256 this cue to switching to a more promising alterna-
257 tive goal or means. Indeed, when research partic-
258 ipants were asked to form implementation
259 intentions that linked negative feedback on the
260 ongoing goal striving to immediately switching
261 to a different goal or means or to reflecting on the
262 quality of the received failure feedback on the
263 ongoing goal striving, adaptive disengagement
264 from goals and means was found to occur more
265 frequently than for participants who had only
266 formed respective goal intentions or had formed
267 no intentions at all.

268 Finally, forming implementation intentions can
269 help prevent resource depletion as it enables indi-
270 viduals to engage in automated goal striving and
271 behavior control that does not require effortful
272 deliberation (e.g., forming implementation inten-
273 tions to ask for available vegetarian dishes when a
274 waiter takes one's order). As a consequence, the
275 self should not become depleted when goal striving
276 is regulated by implementation intentions.
277 Indeed, in studies using different ego-depletion
278 paradigms, research participants who used imple-
279 mentation intentions to self-regulate performance
280 on a difficult first task did not show reduced self-
281 regulatory capacity in a subsequent task.

282 But how much willpower is actually afforded
283 by forming implementation intentions? Any self-
284 regulation strategy that claims to facilitate goal
285 striving has to prove itself under conditions in
286 which people commonly fail to demonstrate will-
287 power (Gollwitzer 2014). Such conditions are
288 manifold (e.g., when one's competencies are chal-
289 lenged, opponents interfere with one's goal striving),
290 but self-regulation of goal striving becomes
291 particularly difficult when habitual responses are
292 in conflict with initiating and executing the
293 needed goal-directed responses that are instru-
294 mental to goal attainment. Can the self-regulation
295 strategy of forming if-then plans help people to let
296 their goals win out over their habitual responses?
297 By assuming that action control by implementa-
298 tion intentions is immediate and efficient and
299 adopting a simple horserace model of action control,
300 people might be able to break habitual

301 responses by forming implementation intentions
302 (e.g., if-then plans that spell out a response con-
303 trary to the habitual response to the critical situa-
304 tion). Still, if the habitual response is based on
305 strong habits (e.g., smoking), and the if-then
306 guided response is based on weak implementation
307 intentions, the habitual response should win over
308 the if-then planned response. However, when
309 weak habits are in conflict with strong implemen-
310 tation intentions, the reverse should be true. This
311 implies that controlling behavior based on strong
312 habits by forming implementation intentions
313 requires that these if-then plans are very strong
314 as well.

315 The strengthening of if-then plans can be
316 achieved in various ways: one pertains to creating
317 particularly strong links between situational cues
318 (if-component) and goal-directed responses (then-
319 component), for instance, by asking participants
320 to use mental imagery. Alternatively, one may
321 tailor the critical cue specified in the if-part of an
322 implementation intention to personally relevant
323 reasons for the habitual behavior one wants to
324 overcome and then link this cue to an antagonistic
325 response (e.g., if I feel lonely, then I will put on the
326 music in the living room rather than snack in the
327 kitchen). Also, certain formats of implementation
328 intentions (i.e., replacement and ignore imple-
329 mentation intentions) seem to be more effective
330 in fighting strong habits than other if-then plans
331 (e.g., negation implementation intentions). And
332 finally, stronger implementation intention effects
333 are observed when the respective goals are framed
334 as approach rather than avoidance goals and when
335 goals and plans match in their self-regulatory ori-
336 entation (i.e., either promotion or prevention).
337 Pertaining to the discussion of whether strong
338 habits can be broken by implementation inten-
339 tions, one should keep in mind that behavior
340 change is possible without changing bad habits;
341 one may also focus on building new habits in new
342 situational contexts. With respect to this latter
343 approach, implementation intentions can guide
344 goal striving without having to outrun habitual
345 responses. The delegation of control to situational
346 cues principle, on which implementation intention
347 effects are based, can then unfold its facilitative
348 effects on goal striving in an undisturbed manner.

349 Trying to achieve behavior change by solely
350 forming implementation intentions however for-
351 gets that effective behavior change demands a
352 change in terms of both setting new goals and
353 preparing the respective goal striving by forming
354 implementation intentions. But how can people
355 best select and commit to new goals? Oettingen
356 (2012) has developed a self-regulation strategy of
357 goal setting, called mental contrasting of future
358 and reality that allows people to strongly commit
359 to achieving desired and feasible future outcomes.
360 Specifically, in mental contrasting, people ima-
361 gine the attainment of a desired future (e.g., regu-
362 lar exercise) and then reflect on obstacles of
363 present reality that stand in the way of attaining
364 the desired future (e.g., not setting aside enough
365 time). Given that the perceived chances of success
366 (expectations of success) are high, people will
367 actively commit to and strive toward reaching
368 the desired future.

369 The behavior change intervention called MCII
370 (Oettingen and Gollwitzer 2010) combines men-
371 tal contrasting (MC) with forming implementa-
372 tion intentions (II). To unfold their beneficial
373 effects, implementation intentions require that
374 strong goal commitments are in place, and mental
375 contrasting creates such strong commitments.
376 Implementation intentions are also found to
377 show enhanced benefits when the specification
378 of the if-component is personalized, and mental
379 contrasting guarantees the identification of per-
380 sonally relevant obstacles that can then be speci-
381 fied as the critical cue in the if-component of an
382 implementation intention. Finally, mental
383 contrasting has been found to create a readiness
384 for making plans that link obstacles of present
385 reality to instrumental goal-directed behaviors.

386 In recent intervention studies with middle-aged
387 women, participants were taught the cognitive
388 principles and individual steps of the MCII self-
389 regulation strategy. Specifically, in one study, par-
390 ticipants were asked to apply MCII by themselves
391 to the wish of exercising more. Participants were
392 free to choose whatever form of exercising they
393 wished to engage in, and they were encouraged to
394 anticipate exactly those obstacles that were per-
395 sonally most relevant. Finally, they had to link
396 these obstacles to exactly those goal-directed

397 responses that personally appeared to be most
398 instrumental. Teaching the MCII technique
399 enhanced exercise more than only providing rele-
400 vant health-related information (i.e., information-
401 only control intervention). Participants in the
402 MCII group exercised nearly twice as much: an
403 average of 1 h more per week than participants in
404 the information-only control group. This effect
405 showed up immediately after the intervention,
406 and it stayed stable throughout the entire period
407 of the study (16 weeks after the intervention).
408 Conducting the same MCII intervention was also
409 effective for promoting healthy eating in middle-
410 aged women (i.e., eating more fruits and vegeta-
411 bles). The achieved behavior change persisted
412 even over a period of 2 years. Follow-up research
413 targeting the eating habit of unhealthy snacking
414 was conducted with college students. It was
415 observed that MCII worked for both students
416 with weak and strong such habits, and it was
417 more effective than either mental contrasting or
418 forming implementation intentions alone.

419 Importantly, MCII geared toward engaging in
420 physical exercise, and eating healthy turned out to
421 be effective with clinical groups as well. For
422 instance, a study with inpatients diagnosed with
423 schizophrenia observed that MCII helped the
424 patients translate their exercising intentions into
425 action, and this was found to be especially the case
426 when MCII was applied in an autonomy-focused
427 hospital setting as compared to a highly structured
428 setting. Moreover, a MCII intervention improved
429 stroke patients' physical activity and weight loss
430 over 1 year compared to control groups that were
431 informed on how to eat better and engage in more
432 physical exercise. Finally, MCII was observed to
433 benefit chronic back pain patients in increasing
434 their mobility over a period of 3 months, whereby
435 physical mobility was assessed by objective mea-
436 sures (e.g., bicycle ergometer test) as well as self-
437 reported physical functioning, and MCII helped
438 hazardous drinkers who wanted to drink less alco-
439 hol to attain their goal.

440 In sum, MCII qualifies as a cost- and time-
441 effective self-regulation intervention to enhance
442 healthy and to prevent unhealthy behaviors. It
443 helps to solve the two central tasks of goal pursuit:
444 forming strong goal commitments on the one

445 hand and following up on these commitments by
 446 effective goal implementation, on the other. Not
 447 surprisingly, then, combining mental contrasting
 448 with implementation intentions offers additional
 449 advantages compared to each strategy alone.
 450 Research on MCII has stimulated the develop-
 451 ment of an MCII app (see woopmylife.org) that
 452 is described in Oettingen (2014).
